(54) Projector apparatus

(57) A projector apparatus comprises an image signal processor (2) for generating color drive signals of at least four channels, which correspond to at least four kinds of colors including colors selected according to the spectrum of a light source, from the three primary color image signals; a light-splitting device for splitting the light from the light source into at least four kinds of light

according to the colors corresponding to the color drive signals generated in the image signal processor (2); light valves (LB), each of which comprises a liquid crystal element driven by the color drive signal for modulating each light component split from that of the light source by the light-splitting device; and a combining device for combining the light components modulated by the light valves.

FIG.3

EP 0 843 487 A1

## Description

This invention relates to projector apparatus.

In recent years, there are becoming widespread projection type projector apparatuses, each of which uses three TFT (Thin Film Transistor) liquid crystal display panels corresponding to the three primary colors of RGB (red, green and blue), (hereinafter referred to as a 3-plate projector apparatus). This projector apparatus projects images on a large screen hung on the wall or a semitransparent screen such as a Fresnel lens to provide realistic images on the large screen appealing strongly to the watchers. This projector apparatus comprises an optical system and a driving control system of the optical system that are all housed in the apparatus. The light emitted from a light source of the optical system is splitted into RGB colors, then modulated by light valves, each of which comprises a liquid crystal panel, according to the drive signals generated by the driving control system, then combined again to form color images.

Figure 1 is a schematic diagram illustrating an example of the optical system of a previously proposed projector apparatus.

The light W emitted from the light source 31 is incident on the dichroic mirror 32 to be splitted into red light R, green/blue light G/B, for which the light R is reflected and the light G/B is transmitted.

The light R splitted by reflecting on the dichroic mirror 32 is further reflected by the mirror 33, then modulated by the light valve LB11 that controls transmission of the red light and led to the dichroic mirror 34. The light G/B transmitted through the dichroic mirror 32 reaches the dichroic mirror 35, and is splitted into lights G and B. The light G splitted by reflecting on the dichroic mirror 35 is modulated in the light valve LB12 that controls transmission of green light, then led to the dichroic mirror 34 and reflected therefrom so as to be combined with the light R and led to the dichroic mirror 37 as a light R/G. In the meantime, the light B transmitted through the dichroic mirror 35 is modulated by the light valve LB13 that controls transmission of blue light, then reflected by the mirror 36 and led to the dichroic mirror 37.

The dichroic mirror 37 transmits the light R/B led from the dichroic mirror 34 and reflects the light B reflected from the mirror 36, so that the lights with those 3 colors are combined. The combined light RGB is enlarged through a projection lens 38 and projected on, for example, a screen hung on the wall.

The light source 31 used for the projector apparatus shown in Fig. 1 has emission characteristics with various spectral distributions depending on the lamp in use. Therefore, when selecting three chromaticity points meeting the EBU (Europe Broadcast Union) Standard for each of RGB for a light source having a spectral distribution, for example, as shown in Fig. 2, it becomes difficult to reproduce the color correctly because the green color purity is changed by the color (orange) represented by the spectrum peak generated around the wavelength of 590 nm.

resented by the spectrum peak generated around the wavelength of 590 nm.

To avoid this, there is an idea to cut this orange light to improve the color purity. In this case, however, the efficiency to use the light from the light source is lowered, causing the dynamic range to be narrowed to make the degree of whiteness become insufficient.

Conventionally, when priority is given to the color purity over others, the efficiency to use light is lowered. On the contrary, when the efficiency to use light is improved with the strong light generated around the wavelength of the green light being included in the green region or red region, the color purity must be sacrificed to some extent depending on the emission characteristics of the lamp used as the light source.

According to one aspect of the invention there is provided a projector apparatus as set forth in claim 1.

According to another aspect of the invention there is provided a projector apparatus comprising a light source, an optical system comprising a dichroic mirror as a light-splitting device for splitting for the light emitted from the light source into lights with specified colors and light valves for carrying out optical modulation of the splitted lights; and a driving processing system for generating color drive signals for driving the light valves according to color image signals, wherein the driving processing system includes a drive signal generator for generating at least four channels of the color drive signals from color image signals of the three primary colors, each of the color drive signals corresponding to at least four kinds of colors including colors selected according to the spectrum of the light source, and the optical system includes the light-splitting device for splitting the light from the light source into at least four lights according to the colors corresponding to the color drive signals generated by the drive signal generator; light valves for carrying out optical modulation of the splitted lights, for which the light from the light source is splitted by the light-splitting device, according to the color drive signals; and a combining device for combining the lights modulated by the light valves. According to a preferred form of implementation of the invention, at least four color drive signals corresponding to required chromatic points according to the light source spectral distribution are generated from inputted image signals, and four light valves to be driven by the color drive signals are provided. Thus, the fourth light valve is driven by a fourth color drive signal in addition to the three light valves driven by three kinds of color drive signals corresponding to the three primary colors of RGB, so that the efficiency of using the light source can be improved and the color reproduction range can be expanded significantly. Consequently, even when monitoring images of an ordinary image source, the image can be represented at points where both saturation and luminance on the luminance axis are higher than those of the previously proposed projector apparatus.

Furthermore, more improved representation of lu-

The invention will now be further described, by way of illustrative and non-limiting example, with reference to the accompanying drawings, in which:

Fig. 5 is a schematic diagram illustrating the optical system in the embodiment.

The RGB three primary color signals supplied from the image source 30 are supplied to the image signal processor 2. This image signal processor 2, as will be described later more in detail, generates and outputs drive signals  $R_D$ ,  $O_R_D$ ,  $G_D$ , and  $B_D$  corresponding to the four colors (e.g., red, orange, green, and blue) from the RGB three primary color signals in this embodiment. This is to effectively use the light source having a strong emission spectrum in the orange color region. The G signal is also supplied to the synchronous circuit 3 and synchronous signals (vertical and horizontal) Sync are separated there.

The conversion processing in the four color converter 2b is executed to enable color information defined by input signals on three channels to be defined by output signals on four channels (4-color). The conversion will therefore result in simply producing infinite number of solutions. To avoid this, any one of the four output colors must be constrained. Then, in this embodiment, the luminance signal Y, which is achromatic, is constrained so that the orange color drive signal  $Or_D$  is determined by 3x4 conversion. When the luminance signal Y is thus constrained, the orange color drive signal  $Or_D$  is obtained with the following expressions.

$$G_D = G - sO_{FD}$$

$$B_D = B - tO_{rD}$$

where a, b, c, p, r, s, and t are coefficients and q is a constant. Values of these coefficients are set to those providing the best color reproduction according to the spectral distribution of the light source or through experiment.

A conversion processing can also be executed so as to generally extend the chromaticity by regarding color reproducibility as important, in which, for example, color difference signal (R-Y) or (B-Y) is constrained to give importance to hue components.

A matrix algebra like conversion processing may also be executed by giving importance to the linearity without using any constraining condition, or a conversion processing may be executed using a lookup table for which non-linear part is taken into consideration.

Hereunder, with reference to Fig. 5, a configuration of the optical system 10 will be described which is driven by the four drive signals  $R_D$ ,  $O_{rD}$ ,  $G_D$ , and  $B_D$  generated by the image signal processor 2.

The light W emitted from the light source 11 is incident on the dichroic mirror 12 and splitted so that the light Or/R in the orange/red region is reflected and the light G/B in the green/blue region is transmitted.

The orange light Or represents the light with a peak at the wavelength of  $590 \pm 15$  nm emitted when using the light source 11 having the emission characteristics shown in Fig. 2. The wavelength of the peak changes according to the emission characteristics of the lamp in use.

The light Or/R splitted by the dichroic mirror 12 is led to the dichroic mirror 13 and further splitted there into the light R in the red region and the light Or in the orange region with the light R being transmitted and the light Or being reflected. The light R is reflected by the mirror 14 and modulated by the light valve LB1 for red color, then led to the dichroic mirror 16. The light Or, after being reflected by the dichroic mirror 13, is reflected again by the mirror 15a and modulated by the light valve LB2 for orange color. The modulated light Or is led to the dichroic mirror 16.

The dichroic mirror 16 is formed to transmit the light R in the red region and reflect the light Or in the orange region, so that the modulated light R and Or are allowed to be combined there and the combined light Or/R is led to the dichroic mirror 17.

In the meantime, the light G/B that has been transmitted the dichroic mirror 12 reaches the dichroic mirror 18 and is splitted into with the light G in the green region and the light B in the blue region with the light G being reflected and the light B being allowed to be transmitted. Then, the light G is further reflected by the mirror 15b, modulated by the light valve LB3 for green color, and then led to the dichroic mirror 19. The light B, after being transmitted through the dichroic mirror 13, is reflected by the mirror 20, then modulated by the light valve LB4

for blue color. The modulated light B then reaches the dichroic mirror 19.

The dichroic mirror 19 is formed to reflect the light G in the green region and transmit the light B in the blue region, so that the modulated lights G and B are combined and the combined light G/B is led to the dichroic mirror 17.

The dichroic mirror 17 is formed to transmit the light Or/R and reflect the light G/B, so that all of the modulated lights with respective colors are combined to generate a full-colored light RGBOr according to the input image signals. This full-colored light flux RGBOr is expanded and projected on a screen S (not illustrated) by the projection lens 21.

Resolution of the image can be improved by subtly changing the positions of the light valves LB1 to LB4 to subtly shift the four spectral components. When trying to improve the resolution with lights of only three colors, remarkable color shifts appear at edges. In contrast with this, use of lights with four or more colors as described above can reduce such color shifts with some way of combining the lights and improve the resolution to obtain clear images.

As described above, four or more driving signals are generated for four or more colors according to input RGB three primary colors by taking redundancies of luminance and hue into consideration. This enables reproduction of chromaticity points with high luminance and high saturation, which have been impossible in the prior proposal, as well as expansion of the color reproduction range and fine representation within the color reproduction range with improvement in the gradation, resolution, and peak luminance of images.

In this embodiment, an example is explained in which, for example, four drive signals corresponding to four kinds of colors are generated from the RGB three primary color signals to drive the four light valves. However, the number of drive signals and the light valves may be four or more, because the number of these items may be increased according to the spectral distribution of the light source when the efficiency in using light is increased.

## Claims

### 1. A projector apparatus comprising:

- a light source;
- an optical system including means for splitting the light emitted from said light source into lights with specified colors and light valves for carrying out optical modulation of the splitted lights; and
- a driving processing system for generating color drive signals for driving said light valves according to color image signals,

wherein:

said driving processing system includes drive signal generating means for generating at least four channels of said color drive signals from color image signals of three primary colors, each of said color drive signals corresponding to at least four kinds of colors including colors selected according to the spectrum of said light source, and

said optical system includes:

light-splitting means for splitting the light from said light source into at least four lights according to the colors corresponding to said color drive signals generated by said drive signal generating means;

light valves for carrying out optical modulation of the splitted lights, for which the light from said light source is splitted by said light-splitting means, according to said color drive signals; and

combining means for combining said lights modulated by said light valves.

2. A projector apparatus as defined in claim 1, wherein each of said color drive signals is a signal for driving each of light valves corresponding to RGB three primary colors and a fourth color selected according to the emission spectral distribution of said light source.
3. A projector apparatus as defined in claim 2, wherein the wavelength of said fourth color is within  $590 \pm 15$  nm.
4. A projector apparatus as defined in claim 1, wherein said color drive signal is generated according to the luminance signal and the color difference signal of the color image signals input to said projector apparatus.
5. A projector apparatus as defined in claim 1, wherein said drive signal generating means generates at least four types of said color drive signals with said luminance signal of said color image signals being used as a condition of constraint.
6. A projector apparatus as defined in claim 1, wherein said drive signal generating means generates at least four types of said color drive signals with said color difference signal of said color image signals being used as a condition of constraint.
7. A projector apparatus as defined in claim 1, wherein said drive signal generating means carries out a matrix algebra like conversion processing of signals by giving importance to linearity to generate at least four types of said color drive signals.
8. A projector apparatus as defined in claim 1, wherein said drive signal generating means carries out conversion processing of signals using look-up tables for which non-linearity is taken into consideration to generate at least four types of said color drive signals.
9. A projector apparatus as defined in claim 1, wherein each of said light valves comprises a polarizing plate and a liquid crystal panel.
10. A projector apparatus as defined in claim 1, wherein a dichroic mirror is used as said light-splitting means.
11. A projector apparatus as defined in claim 1, wherein a dichroic mirror is used as said combining means.
